Sheet metal forming includes treatments such as bending, spinning, drawing, or stretching implemented by dies or punching tools. Forming is mostly performed on a press and parts are formed between two dies. The sheet metal forming process is straightforward: A sheet of metal is cut out from a stock metal to create individual blanks.

Introduction Sheet metal is simply metal formed into thin and flat pieces. It is one of the fundamental forms used in metalworking, and can be cut and bent into a variety of different shapes. Countless everyday objects are constructed of the material.

~~SHEET METAL FORMING — AN INTRODUCTION~~

Sheet metal forming is the process of turning a flat sheet of steel (or other material, such as aluminium or copper or titanium) into a complex 3D shape, such as those seen in vehicles or aircraft. Compare this to sheet metal fabrication, in which sheets of steel are bent or folded, into simple shapes, such as a folded box or enclosure.

Sheet metal is available in flat pieces or coiled strips. The coils are formed by running a continuous sheet of metal through a roll slitter. In most of the world, sheet metal thickness is consistently specified in millimeters. In the U.S., the thickness of sheet metal is commonly specified by a traditional, non-linear measure known as its gauge.

~~Sheet metal — Wikipedia~~

Sheet forming: Sheet metal forming involves forming and cutting operations performed on metal sheets, strips, and coils. The surface area-to-volume ratio of the starting metal is relatively high. Tools include punch, die that are used to deform the sheets. Classification of basic sheet forming processes

Sheet forming is used to produce curved panels for large structures such as the fuselage. The process involves clamping the ends of rolled metal sheet (usually thinner than 6 mm) and then stretching over a forming block to the desired shape. The pressure used to stretch the sheet is applied through male or female dies or both.
